

## **Tutorial 9 – Image Processing**

### **1. Implement an RGB to Hue conversion in C.**

- Read an input camera image in RGB format
- Convert every pixel to a HSI values.
- For a given desire hue value and if I (intensity) is above a threshold, generate a binary truth image, where a pixel is true if its hue is within a fixed range of the desired hue

Example:

### **2. Implement the Laplace and Sobel edge detectors as functions in C.**

- Image input and output parameters should be of type BYTE \*
- Make sure that the output value will stay in range 0..255, e.g. by limiting the max (min values)
- Use local neighbor pixels to calculate new value for each pixel
- Do not use sqrt or other compute-intense functions. Use sum of absolute values instead.

Laplace 3x3:

|    |    |    |
|----|----|----|
| 0  | -1 | 0  |
| -1 | 4  | -1 |
| 0  | -1 | 0  |

Sobel 3x3 (x-direction and y-direction)

|    |   |   |    |    |    |
|----|---|---|----|----|----|
| -1 | 0 | 1 | 1  | 2  | 1  |
| -2 | 0 | 2 | 0  | 0  | 0  |
| -1 | 0 | 1 | -1 | -2 | -1 |

**Note:** Sobel = | Sob<sub>x</sub> | + | Sob<sub>y</sub> |

### 3. Implement a thinning operator for a binary image as a function in C.

3x3 Kernels:

|   |   |   |
|---|---|---|
| 0 | 0 | 0 |
|   | 1 |   |
| 1 | 1 | 1 |

|   |   |   |
|---|---|---|
|   | 0 | 0 |
| 1 | 1 | 0 |
|   | 1 |   |

If a pixel matches exactly the given 3x3 kernel, then it is deleted (set to black); otherwise it stays unchanged.

For every pixel, you need to apply all four 90°-rotation variations of each of the two kernels, so 8 kernels altogether are applied to each pixel.

The output for each pixel is either 0 or 1.

Example:
